References External links Category:2001 software Category:Windows-only freeware Various types of clutch release mechanisms for use in automotive engines are known in the art. One common type of release mechanism is a push-type release mechanism, where a release member is manually activated. Alternatively, a bi-metallic spring clutch release mechanism is a release mechanism which is mechanically activated via the centrifugal force exerted on the centrifuge during engine operation. While the direct bi-metallic spring type clutch release mechanism offers the advantages of reduced weight and simplicity over a conventional push-type clutch release mechanism, this direct bi-metallic spring type clutch release mechanism is prone to a sudden and unexpected clutch release when the engine is either accelerating or decelerating at high rpm. This early release arises from the characteristics of the bi-metallic spring clutch release mechanism. The length of the bi-metallic spring is dependent on the rpm of the engine, and is insufficient to mechanically break the connection between the master clutch and the transmission in the event of an accident. In addition, even in the non-accident state, the bi-metallic spring clutch release mechanism requires a minimum of 20% of engine throttle to be released from the transmission. It is known to provide a retaining plate which moves in response to centrifugal force and which causes a release mechanism to be retained in the engaged position in the event of an accident. This approach is, however, very complex and requires a substantial amount of space. Although automatic bi-metallic spring clutch release mechanisms have been devised which are activated by the clutch pedal when the clutch pedal is depressed, these typically require a high clutch pedal force and do not provide any means for releasing the clutch before the clutch pedal is fully depressed. It is, therefore, desirable to provide an automatic bi-metallic spring clutch release mechanism for an automotive engine which is not prone to an early and unexpected clutch release when the engine is either accelerating or decelerating. It is also desirable to provide an automatic bi-metallic spring clutch release mechanism which releases the clutch under predetermined conditions, regardless of the position of the clutch pedal. In addition, it is desirable to
